**Develop methods and concepts to deal with compound
and unexpected extreme events**

Swiss national adaptation Strategy

Regional case studies:

- Force people to think the unthinkable
- Identify blind spots

PROJECT CASE STUDIES

1. Alpine area

- Protective forest in the Val Mesolcina
- Extended drought over two consecutive Seasons (winter, summer), storm in the year before

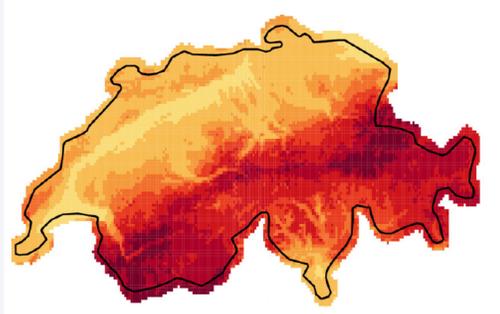

→ Can drought + bark beetle + fire risk lead to a loss of protective function?

2. Swiss Plateau

- Urban area (Basel)
- Multi-year heat and drought event(s)

→ Can consecutive extreme droughts lead to a collapse of interlinked urban systems (water, energy, transport)?

METHODOLOGICAL CONCEPT

Climate scenarios
(CH2018)

Recommendations
for adaptation

Define trigger event

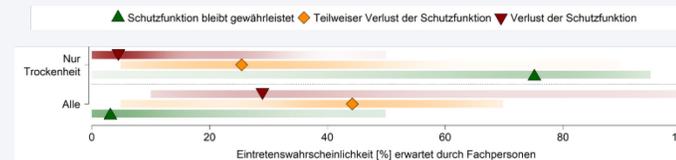

Stakeholders

- Survey
- Interviews

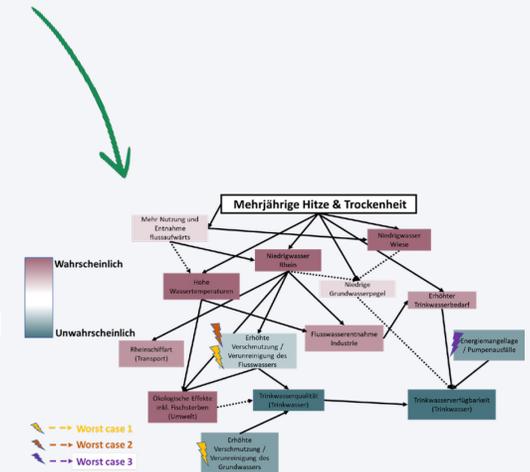

Upscale results

Analysis

- Probabilities
- Process flowcharts

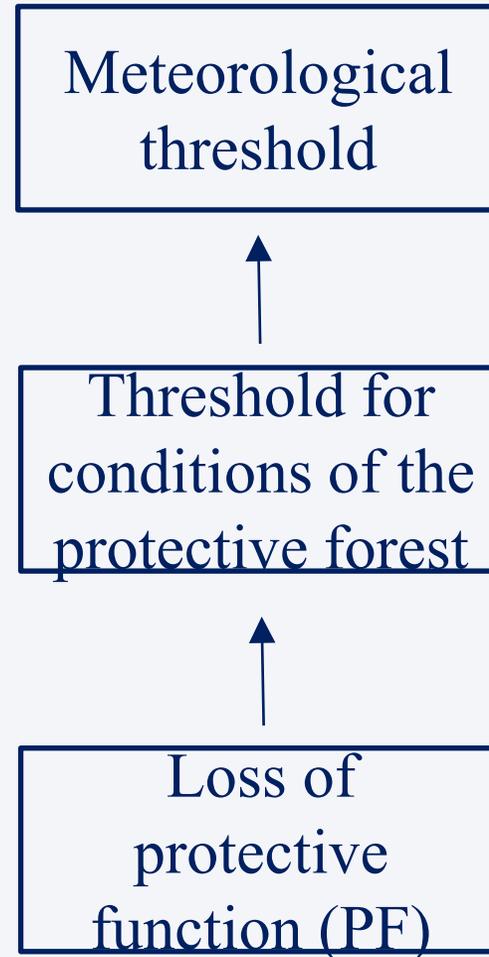

SURVEY: TOP-DOWN AND BOTTOM-UP APPROACHES

Top-down approach

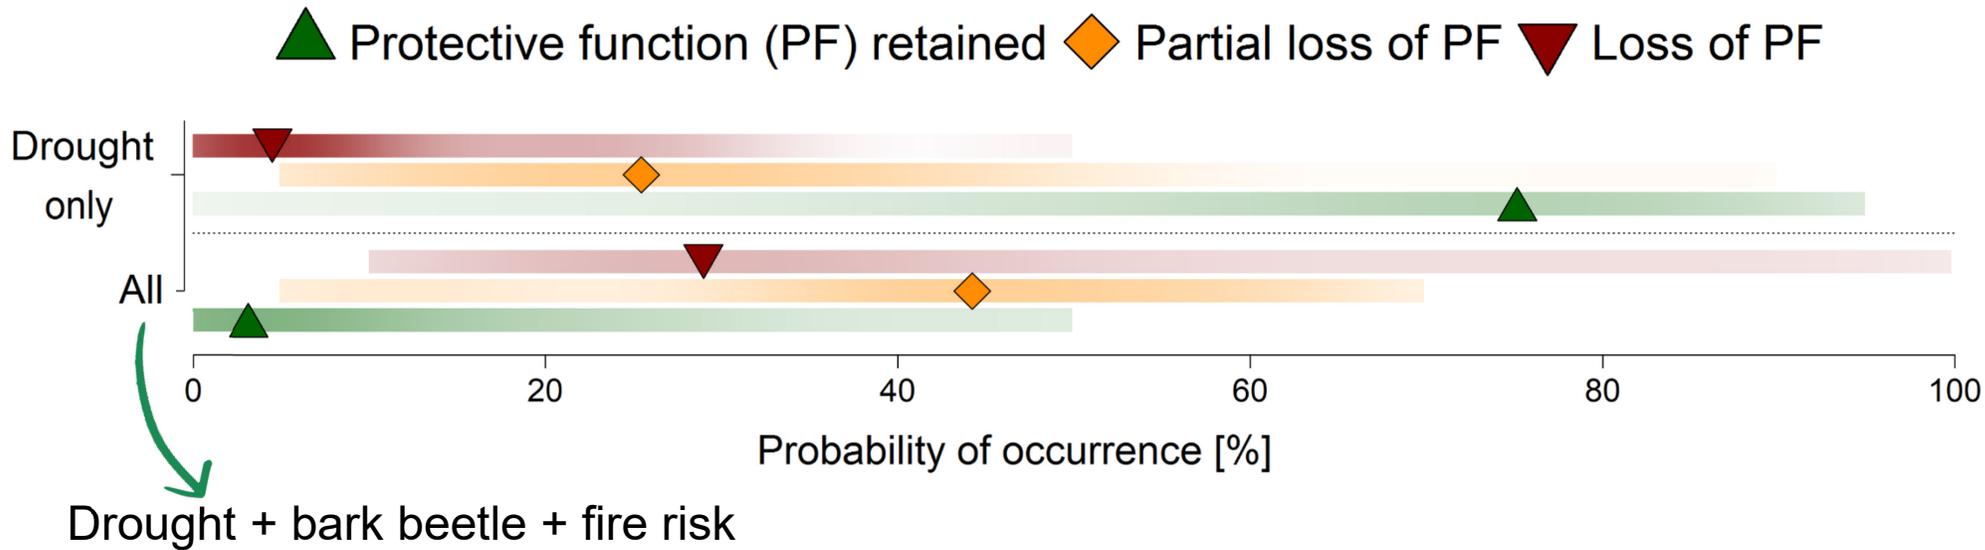

Bottom-up approach

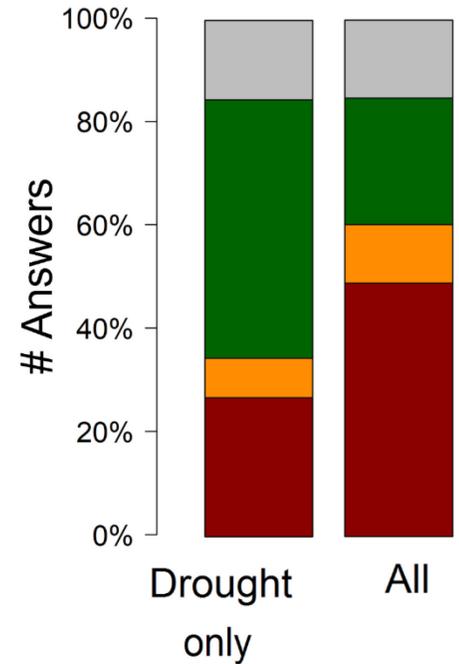

ALPINE CASE STUDY: KEY RESULTS

«Top-down» approach

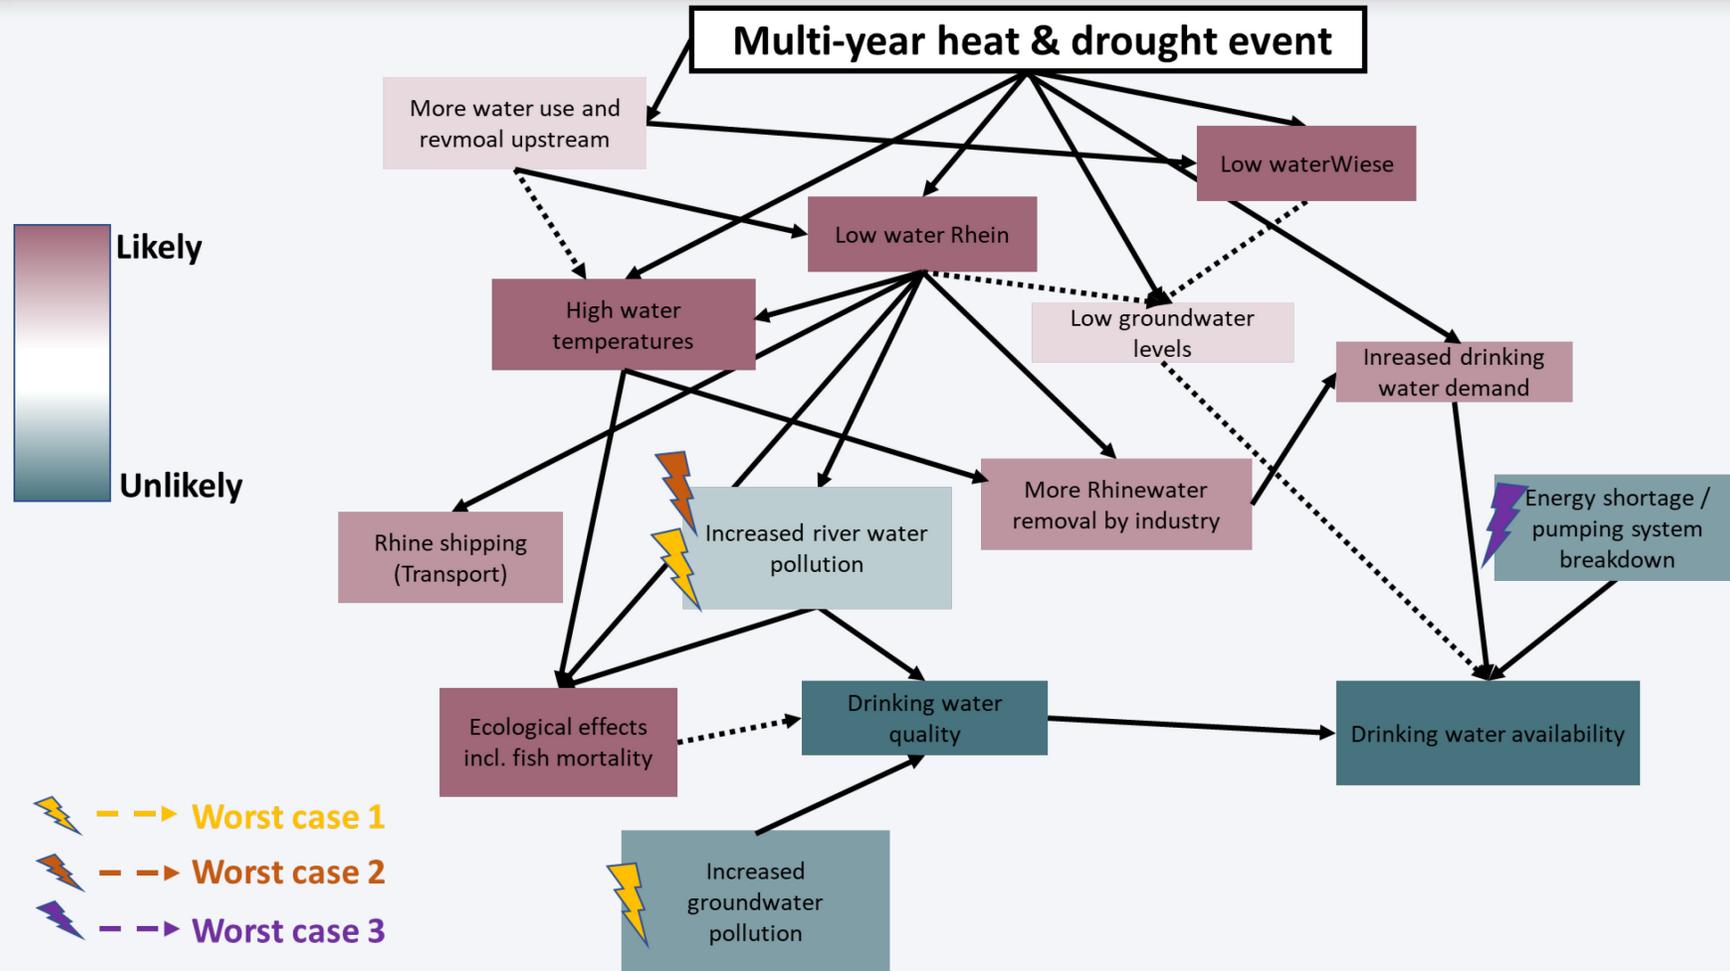

«bottom-up» approach

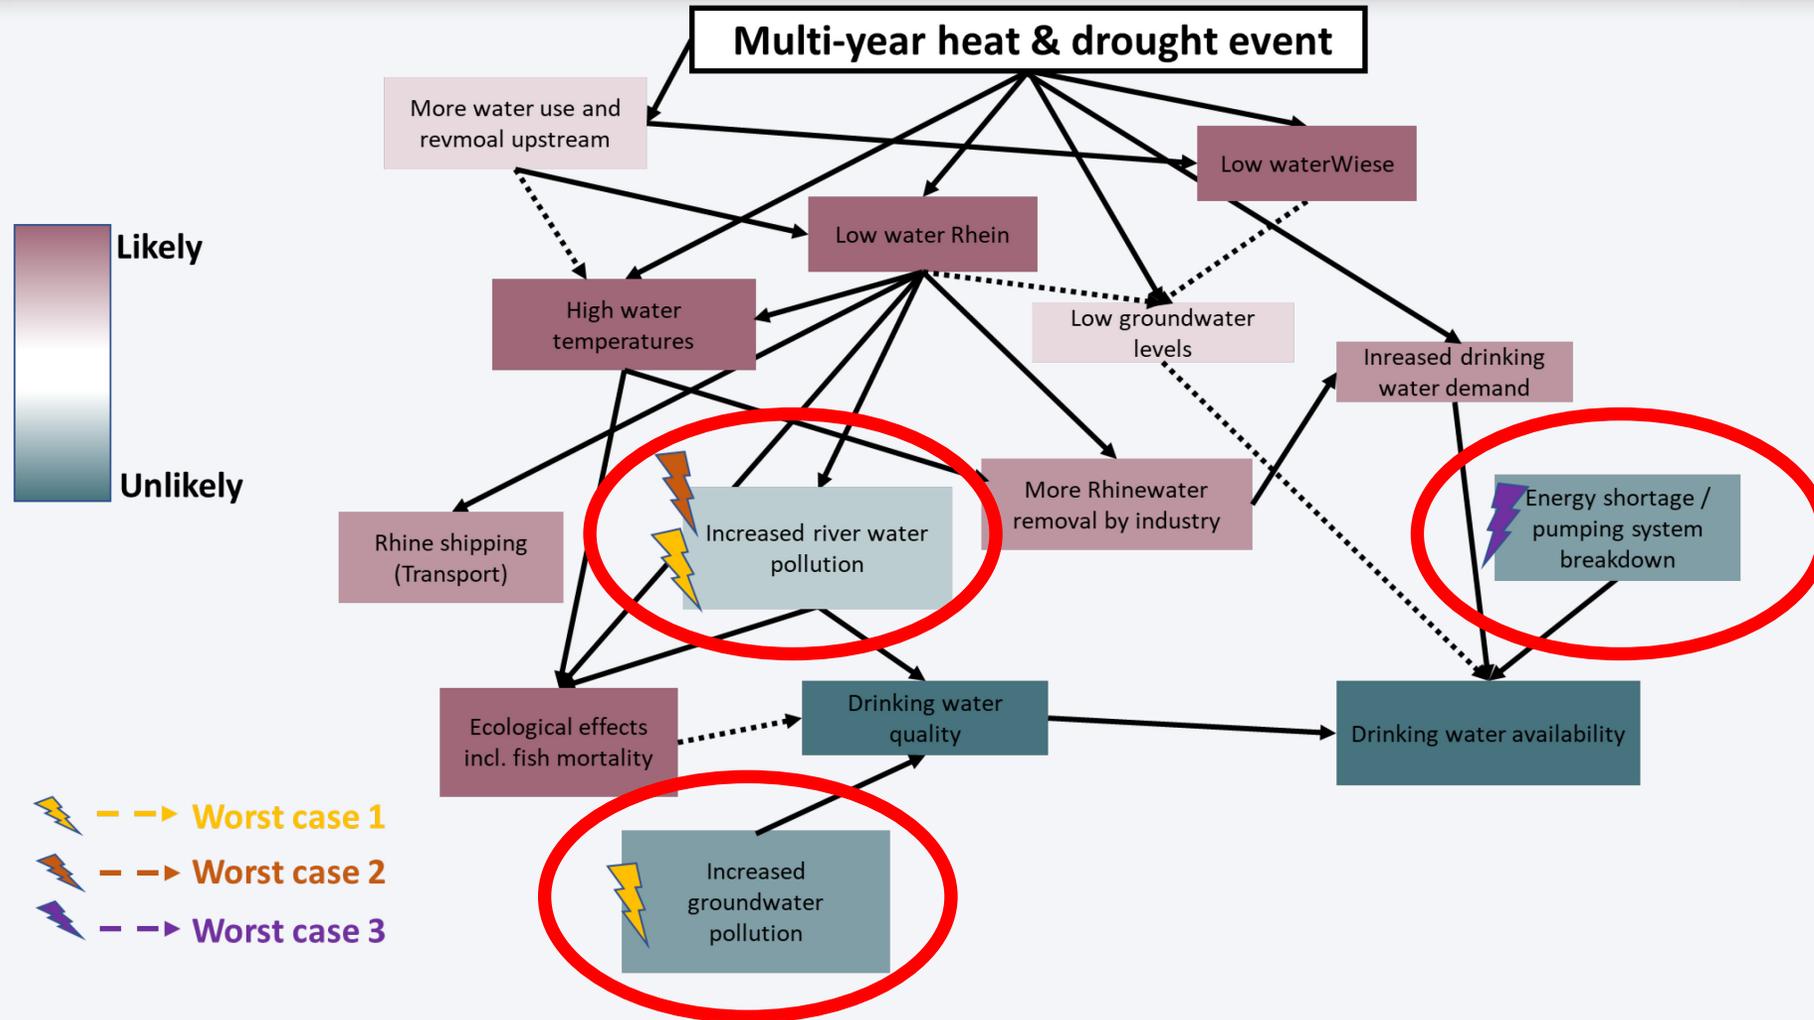

Compound-cascade reduces chance of «no harm» case to 5-20%

URBAN CASE STUDY: KEY RESULTS (DRINKING WATER SYSTEM)

Drinking water shortage only expected if drought compounds with problems in other systems (energy, environment)

URBAN CASE STUDY: RECOMMENDATIONS FOR ADAPTATION

Prepare for problems during peak demand (pollution, energy shortage)

Two-way elicitation helps to do «blind spot thinking» in a structured way

- 1. Characterize process chains**
 - 2. Survey to elicit numbers and probabilities**
- and / or**

Depends on
system
complexity

Interviews to characterize system interconnections and blind spots

Combined approach (top-down plus bottom-up) helps to identify robust results

Helpful for spotting extreme opinions and tail of distributions

THANK YOU

ALPINE CASE STUDY: RECOMMENDATIONS FOR ADAPTATION

General “forest health” is more important than specific drought / fire actions
